New Connections to the AMPL Modeling Language: Spreadsheets and Callbacks

Optimization applications are often concerned as much with making connections as with building models. This presentation describes two connections recently implemented in the AMPL modeling language and system. A direct spreadsheet connection reads and writes xlsx-format files, defining correspondences between common spreadsheet layouts and AMPL's algebraic data definitions. Support is included for "two-dimensional" spreadsheet tables in

which one index labels the columns and one or more indices label the rows. A solver callback connection enables AMPL's APIs to communicate with algorithms as they are running, uniting the ease of modeling in AMPL with the flexibility of programming to customize algorithmic behavior. This facility can be used to write specialized routines that report progress, change settings, and generate constraints that cut off fractional solutions.

Outline

Direct interface to spreadsheet files

- ❖ Implementation as a new AMPL data-table handler
- ❖ **Example:** Multicommodity network flow

Callbacks from solvers

- ❖ Implementation in AMPL APIs for Python, C++, C#
 - * Python in Jupyter notebooks with AMPL cells
- ❖ **Example:** Custom solver stopping criterion
 - * Optimal pattern selection for roll cutting
- ❖ **Example:** Generation of subtour elimination cuts
 - * Minimum tour (TSP) in a network

Direct Spreadsheet Interface

Read & write any .xlsx file

- ❖ Independent of the spreadsheet software used
- ❖ Works on all popular platforms (Windows, Linux, macOS)
- ❖ Bypasses database drivers such as ODBC

Use existing AMPL data-interface statements

- ❖ **table** for making associations between AMPL model parameters and spreadsheet data
- ❖ **read table** and **write table** for importing and exporting data

Now available . . .

- ❖ *Direct .csv file handler*

Direct spreadsheet interface

Network Flow (*symbolic data*)

Given

P set of products

N set of network nodes

$A \subseteq N \times N$ set of arcs connecting nodes

and

u_{ij} capacity of arc from i to j , for each $(i, j) \in A$

s_{pj} supply/demand of product p at node j , for each $p \in P, j \in N$
> 0 implies supply, < 0 implies demand

c_{pij} cost per unit to ship product p on arc (i, j) ,
for each $p \in P, (i, j) \in A$

Direct spreadsheet interface

Network Flow (*symbolic model*)

Determine

X_{pij} amount of commodity p to be shipped from node i to node j ,
for each $p \in P$, $(i, j) \in A$

to minimize

$$\sum_{p \in P} \sum_{(i, j) \in A} c_{pij} X_{pij}$$

total cost of shipping

subject to

$$\sum_{p \in P} X_{pij} \leq u_{ij}, \text{ for all } (i, j) \in A$$

total shipped on each arc must not exceed capacity

$$\sum_{(i, j) \in A} X_{pij} + s_{pj} = \sum_{(j, i) \in A} X_{pji}, \text{ for all } p \in P, j \in N$$

shipments in plus supply/demand must equal shipments out

Direct spreadsheet interface

And There's More . . .

All existing features supported

- ❖ Indexed collections of tables
- ❖ Dynamic file, range & header names in tables
- ❖ `read table`, `write table` in loops and conditionals

New spreadsheet-specific features

- ❖ Recognize both sheet and range names
- ❖ Properly interpret empty data cells
- ❖ Handle “two-dimensional” spreadsheet tables

Callbacks from Solvers

Generic implementation in AMPL APIs

- ❖ In multiple languages: Python, C++, C#
- ❖ For multiple solvers: CPLEX, Gurobi, Xpress
 - * based on our AMPL-enabled distribution
- ❖ With multiple *generic* callback types: MIPNODE, MIPSOL, ...
 - * *Solver specific* callbacks also available

Sample uses

- ❖ Implementing a solver stopping criterion
 - * optimal pattern selection for roll cutting
- ❖ Adding user-generated constraints
 - * minimum tour (TSP) of a network

Examples in Python

- ❖ Jupyter notebooks with AMPL cells

Pattern Selection for Roll Cutting

Given

- ❖ Raw rolls of a large (fixed) width
- ❖ Demands for various (smaller) ordered widths
- ❖ Selected cutting patterns that may be used

Determine

- ❖ Number of times to cut each pattern

So that

- ❖ Demands are met (or slightly exceeded)
- ❖ *Number of raw rolls cut* is minimized

Roll Cutting

Solution Strategy

Generate many “good” cutting patterns

- ❖ Example: solve knapsack subproblems

Solve integer program using all patterns generated

- ❖ Apply a solver for a “reasonable” amount of time
- ❖ Return the best (possibly optimal) solution found

... using a callback to implement an adaptive stopping rule

Stopping Rule

Data

- ❖ Times $t_1 < t_2 < t_3$ etc.
- ❖ Optimality gap tolerances $g_1 < g_2 < g_3$ etc.

Execution

- ❖ When elapsed time reaches $t_i \dots$
- ❖ Increase the gap tolerance to g_i

Stopping Rule

Implementation Highlights

Stopping rule data in Python dictionary

```
stopdict = { 'time'   : ( 15,   30,   60 ),
              'gaptol' : ( .0002, .002, .02 )
            }
```

Callback class (constructor)

```
class MyCallback(ampls.GenericCallback):
    def __init__(self, stoprule):
        super(MyCallback, self).__init__()
        self._stoprule = stoprule
        self._current = 0
        self._continueOpt = True
    .....
```

Stopping Rule

Implementation Highlights

Callback class (process callback, update gap tolerance)

```
def run(self):
    where = self.getAMPLWhere()
    if where == ampls.Where.MIPNODE:
        runtime = self.getValue(ampls.Value.RUNTIME).dbl
        if runtime >= self._stoprule['time'][self._current]:
            self._continueOpt = True
            return -1
    return 0

def setCurrentGap(self):
    gaptolpct = 100*self._stoprule['gaptol'][self._current]
    stoptime = self._stoprule['time'][self._current]
    print("Increasing gap tolerance to "
          f"{gaptolpct:.2f}% after {stoptime:.1f} seconds")
    ampls_model.setAMPLsParameter(ampls.SolverParams.DBL_MIPGap,
                                   self._stoprule['gaptol'][self._current])
    self._current += 1
```

Stopping Rule

Implementation Highlights

Solve using callbacks

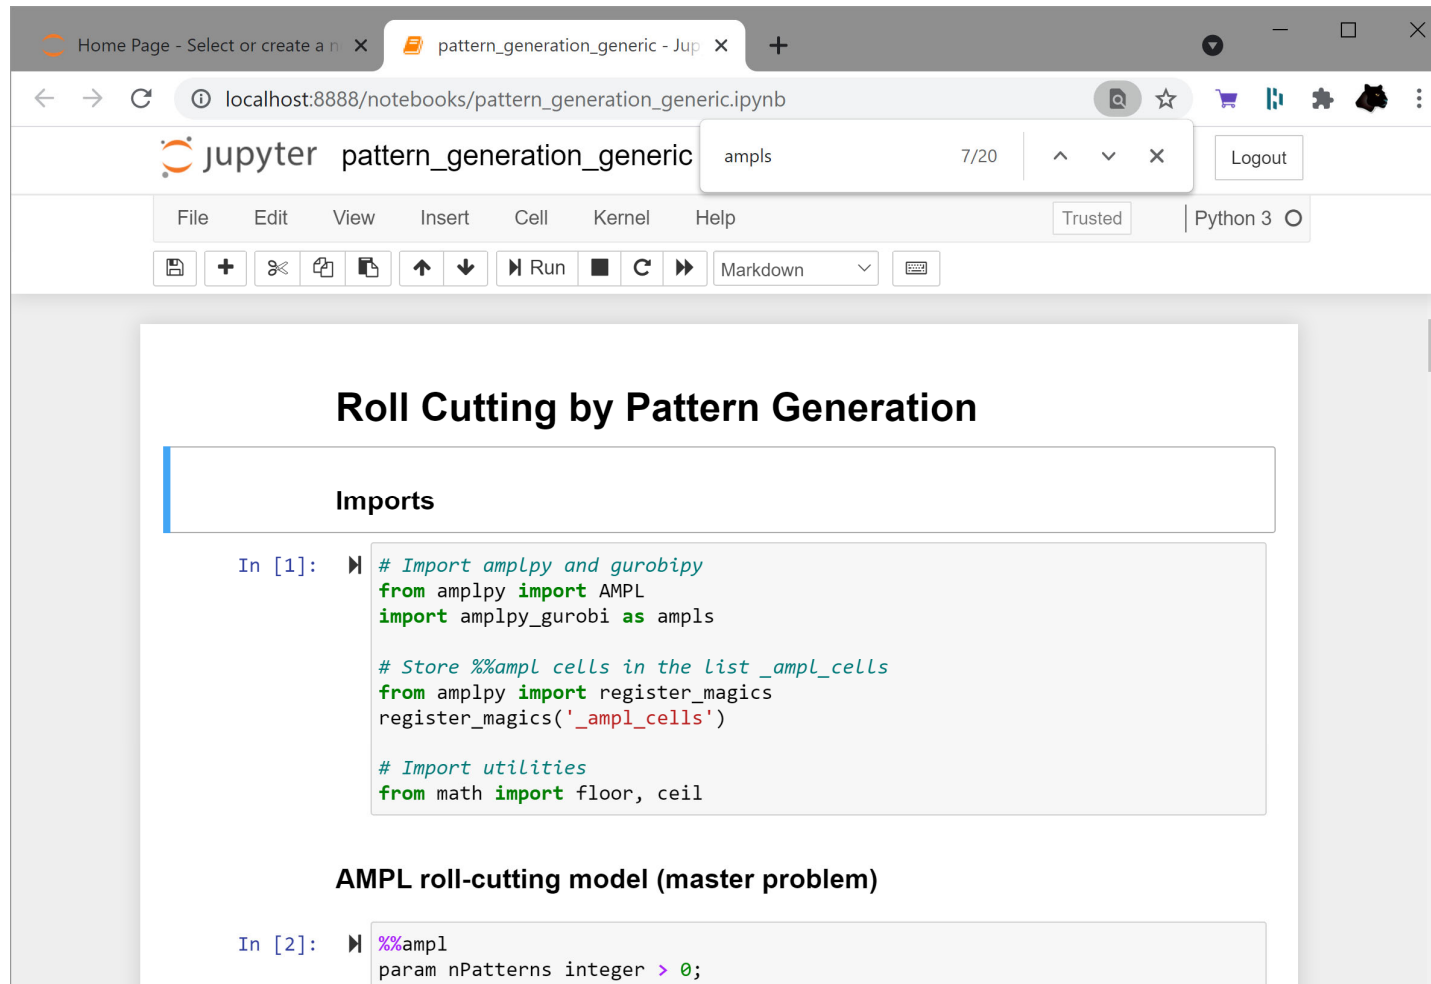

```
# Export
Master.option['relax_integrality'] = 0
ampls_model = Master.exportModel(solver, ["return_mipgap=5"])

# Initialize with stopping rule
callback = MyCallback(stopdict)
ampls_model.setCallback(callback)

# Invoke solver
while callback._continueOpt:
    callback._continueOpt = False
    ampls_model.optimize()
    if callback._continueOpt:
        callback.setCurrentGap()

# Import solution from solver
Master.importSolution(ampls_model)
```

Roll-Cutting Notebook

The screenshot shows a Jupyter Notebook titled "pattern_generation_generic" running on a local server at localhost:8888. The notebook contains two code cells. The first cell, labeled "Imports", contains Python code that imports the 'AMPL' module from 'amplpy', imports 'gurobi' from 'amplpy_gurobi' as 'ampls', registers a magic function for '%ampl' cells, and imports 'floor' and 'ceil' from the 'math' module. The second cell, labeled "AMPL roll-cutting model (master problem)", contains the AMPL command '%ampl param nPatterns integer > 0;'.

Roll Cutting by Pattern Generation

Imports

```
In [1]: # Import amplpy and gurobipy
from amplpy import AMPL
import amplpy_gurobi as ampls

# Store %ampl cells in the list _ampl_cells
from amplpy import register_magics
register_magics('_ampl_cells')

# Import utilities
from math import floor, ceil
```

AMPL roll-cutting model (master problem)

```
In [2]: %ampl
param nPatterns integer > 0;
```

https://ampl.com/dl/Notebooks/patgen_callback.zip

Callbacks from Solvers

Minimum Tour (TSP)

Given

- ❖ A set of locations (“nodes”)
- ❖ Distances between pairs of locations (“arcs”)

Choose

- ❖ A subset of arcs having minimum total distance

So that

- ❖ Exactly two arcs meet each node (*adjacency*)
- ❖ At least two arcs connect every subset of nodes (*subtour elimination*)

Minimum Tour

Solution Strategy

Start with only adjacency constraints

For each feasible solution found,

- ❖ Check for subtours
- ❖ Add an elimination constraint for each subtour found
- ❖ Continue with the optimization

... using a callback to add the elimination constraints

Minimum Tour

Implementation Highlights

Set a few execution parameters

```
solver = "cplex"  
tspFile = "TSP/ch150.tsp"  
PLOTSUBTOURS = True
```

Read TSPLIB file into a dictionary

```
def getDictFromTspFile(tspFile):  
    p = tsp.load(tspFile)  
    nnodes = len(list(p.get_nodes()))  
    formatString = f"{{:0{{ceil(log10(nnodes+1))}}d}}"  
    nodes = {formatString.format(value) : p.node_coords[index+1]  
             for index, value in enumerate(p.get_nodes())}  
    return nodes
```

Implementation Highlights

Create AMPL object, load model and data

```
# Create AMPL object and set solver
AMPL = AMPL()
AMPL.option["solver"] = solver

# Load model in AMPL
tspAMPLModel = _AMPL_cells[0]
AMPL.eval(tspAMPLModel)

# Read TSPLIB file and pass data to AMPL
nodes = getDictFromTspFile(tspFile)

df = DataFrame(index=[('NODES')], columns=['hpos', 'vpos'])
df.setValues(nodes)
AMPL.setData(df, "NODES")
```

Implementation Highlights

Define callback

```
class MyCallback(ampls.GenericCallback):
    def __init__(self):
        # Constructor, simply sets the iteration number to 0
        super().__init__()
        self.iteration = 0

    def run(self):
        try:
            # For each solution
            if self.getAMPLWhere() == ampls.Where.MIPSOL:
                self.iteration += 1
                print(f"\nIteration {self.iteration}: Finding subtours")
                sol = self.getSolutionVector()
                arcs = [xvars[i] for i,value in enumerate(sol) if value > 0]
                subTours = findSubTours(set(arcs), set(vertices))
                if len(subTours) == 1:
                    print("No subtours detected. Not adding any cut")
                    return 0
```

Implementation Highlights

Define callback (cont'd)

```
class MyCallback(AMPL.GenericCallback):
    ...
    def run(self):
        ...
        for subTour in subTours:
            st1 = set(subTour)
            nst1 = set(vertices) - st1
            externalArcs = [(i,j) if i < j else (j,i)
                            for i in st1 for j in nst1]
            varsExternalArcs = [xinverse[(i,j)
                                       for (i,j) in externalArcs]]
            coeffs = [1 for i in range(len(varsExternalArcs))]
            varsExternalArcs = sorted(varsExternalArcs)
            self.addLazyIndices(varsExternalArcs , coeffs,
                               AMPL.CutDirection.GE, 2)

            if len(subTours) == 2:
                return 0
            print("Continue solving")
        return 0
```

Implementation Highlights

Run subtour elimination

```
# Export the model using ampl
model = ampl.exportModel(solver)
model.enableLazyConstraints()

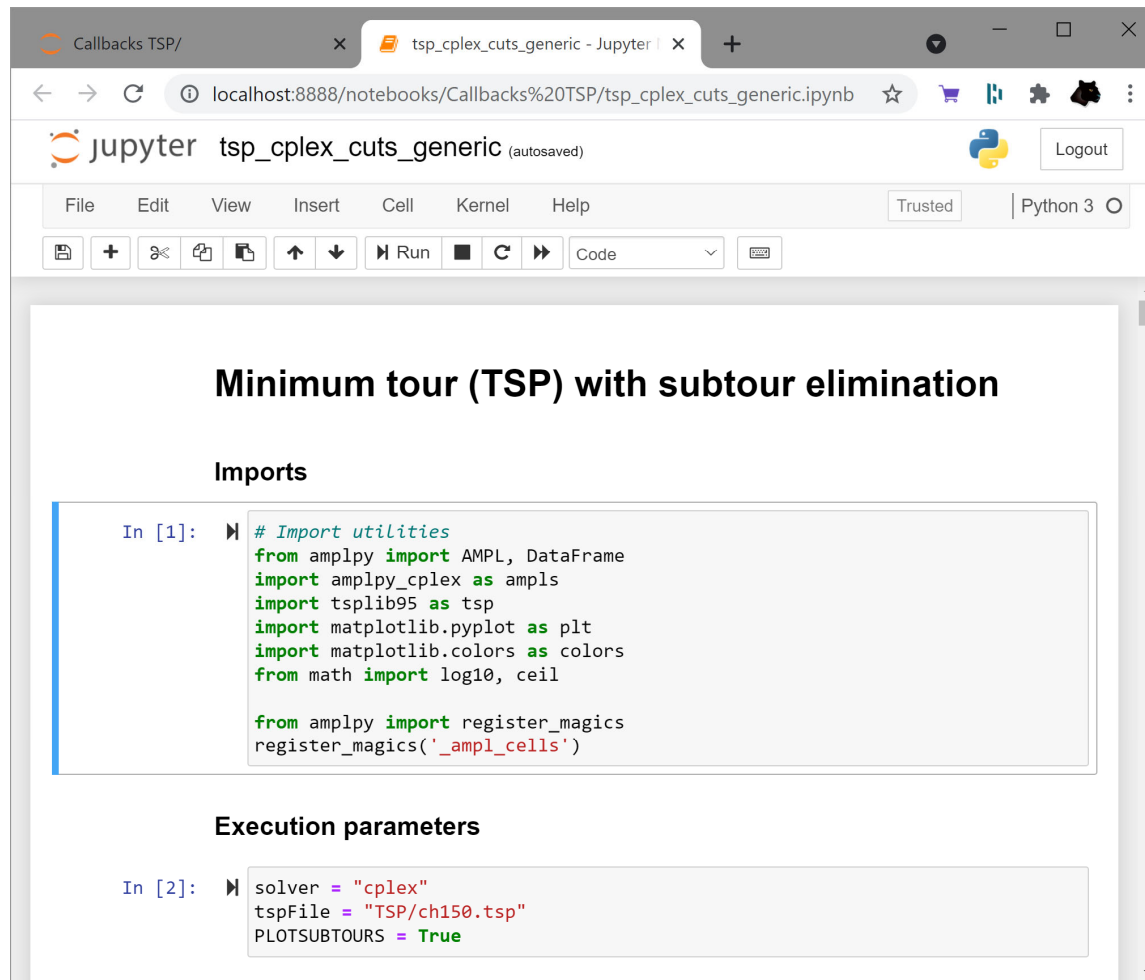

# Get the global maps between solver vars and AMPL entities
varMap = model.getVarMapFiltered("X")
inverse = model.getVarMapInverse()
xvars = ...
xinverse = ...
vertices = ...

# Assign the callback
callback = MyCallback()
model.setCallback(callback)

# Start the optimization
model.optimize()

# Import the solution back to AMPL
ampl.importSolution(model)
```
